Einführung

In vielen Umgebungen müssen Sie einen Access Server konfigurieren, der eingehende Anrufe von Async- und ISDN-Benutzern entgegennehmen kann. Diese Benutzer können sich dann nahtlos mit dem Netzwerk verbinden, als wären sie physisch anwesend. Eine solche Konfiguration wird häufig verwendet, um Benutzern, die unterwegs sind und Telearbeiter sind, sowie für Standorte des Small Office-Home Office (SOHO) Netzwerkverbindungen bereitzustellen.

In diesem Dokument wird beschrieben, wie ein Access Server so konfiguriert wird, dass er eingehende Async- und ISDN-Anrufe auf ISDN T1 PRI-Leitungen akzeptiert. Die Konfiguration bietet die erforderliche Mindestkonfiguration, damit der Netzwerzkugriffsserver (NAS) den Anruf annehmen kann. Sie können dieser Konfiguration je nach Ihren Anforderungen zusätzliche Funktionen hinzufügen.

Voraussetzungen

Anforderungen

Für dieses Dokument bestehen keine speziellen Anforderungen.

Verwendete Komponenten

Die Informationen in diesem Dokument basieren auf den folgenden Software- und Hardwareversionen:

- Cisco AS5300 mit 192 MICA-Modems und acht T1-Ports, auf denen Cisco IOS® Software Release 12.2(5) ausgeführt wird.
- Zwei T1 PRIs.
- Ein PC, auf dem Microsoft Windows ausgeführt wird. Dieser PC verfügt über ein analoges Modem und eine Telefonverbindung zum öffentlichen Switch-Telefonnetz. Der PC wählt die T1 PRI, die mit dem AS5300 verbunden ist.
- Cisco Router der Serien 800 und 1600 mit ISDN BRI-Schaltkreisen. Diese Router sind die ISDN-Wählclients. Die Konfiguration für den Cisco 1600 wird bereitgestellt. Sie können diese Client-Konfiguration auf jeden Router mit BRI-Schnittstelle anwenden.
- Lokale Authentifizierung, Autorisierung und Abrechnung (AAA). Wenn Sie über einen AAA Radius- oder TACACS+-Server verfügen, können Sie mit beiden Servern AAA für eingehende Anrufe bereitstellen.

Hinweis: Die Konfiguration des Cisco 800-Routers ähnelt der Konfiguration des Cisco 1600-Routers und ist nicht in diesem Dokument enthalten.

Die Informationen in diesem Dokument wurden von den Geräten in einer bestimmten Laborumgebung erstellt. Alle in diesem Dokument verwendeten Geräte haben mit einer leeren (Standard-)Konfiguration begonnen. Wenn Ihr Netzwerk in Betrieb ist, stellen Sie sicher, dass Sie die potenziellen Auswirkungen eines Befehls verstehen.

Zugehörige Produkte

Sie können diese Konfiguration mit jedem Router verwenden, der über T1- oder PRI-Karten und interne digitale Modems verfügt (z. B. MICA, NextPort oder Microcom). Alle Router der AS5xxx-Serie mit T1- oder PRI-Karte und digitalen Modems können die Konzepte in dieser Konfiguration verwenden.

Cisco Router der Serie 2600 unterstützen keine internen digitalen Modems. Sie können Router der Cisco Serie 2600 so konfigurieren, dass sie nur ISDN-Anrufe annehmen, sofern der Router über ein T1-, PRI WIC- oder Netzwerkmodul verfügt.

Router der Cisco Serie 3600 unterstützen sowohl ISDN- als auch Modemanrufe. Für Cisco Router der Serie 3600 sind jedoch ein T1-, PRI WIC- oder Netzwerkmodul sowie das NM-xDM Digital Modem Network Module erforderlich.

Sie können diese Konfiguration auch mit E1- oder PRI-Ports ändern. Konfigurieren Sie den E1-Controller mit der Verkabelung, dem Framing und anderen physischen Merkmalen, die Ihr Telco bereitstellt. Die D-Channel-Konfiguration (Schnittstelle Serial x:15 für E1) ähnelt der in diesem Dokument beschriebenen Konfiguration.

Konventionen

Weitere Informationen zu Dokumentkonventionen finden Sie in den [Cisco Technical Tips Conventions](#).

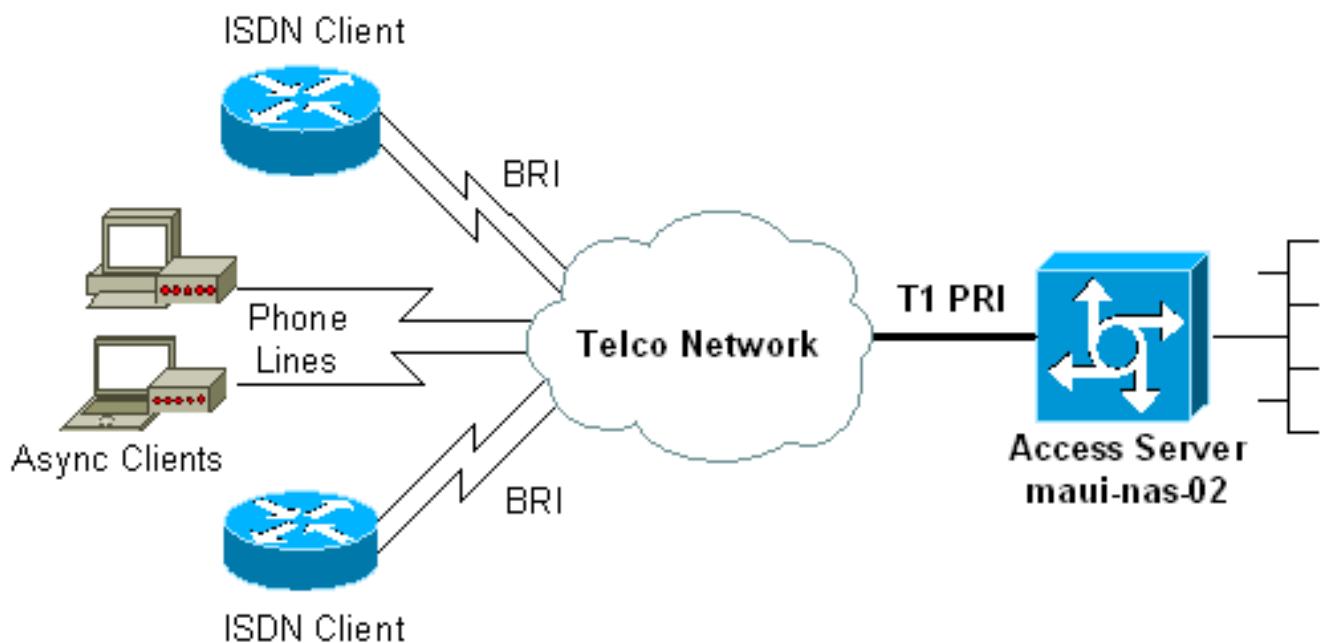

Konfigurieren

In diesem Abschnitt erhalten Sie Informationen zum Konfigurieren der in diesem Dokument beschriebenen Funktionen.

Hinweis: Um weitere Informationen zu den in diesem Dokument verwendeten Befehlen zu erhalten, verwenden Sie das [Command Lookup Tool](#) (nur registrierte Kunden).

Netzwerkdiagramm

In diesem Dokument wird die folgende Netzwerkeinrichtung verwendet:

Überprüfen

Dieser Abschnitt enthält Informationen, mit denen Sie überprüfen können, ob Ihre Konfiguration ordnungsgemäß funktioniert.

Bestimmte **show**-Befehle werden vom [Output Interpreter Tool](#) unterstützt (nur [registrierte](#) Kunden), mit dem Sie eine Analyse der **show**-Befehlsausgabe anzeigen können.

- **show isdn status:** Stellt sicher, dass der Router ordnungsgemäß mit dem ISDN-Switch kommuniziert. Stellen Sie in der Ausgabe sicher, dass der `Layer-1-Status AKTIV` ist und dass der `Layer-2-Status = MULTIPLE_FRAME_ESTABLISHED` angezeigt wird. Dieser Befehl zeigt auch die Anzahl der aktiven Anrufe an. Weitere Informationen finden Sie unter [Verwenden des Befehls show isdn status für die BRI-Fehlerbehebung](#).
- **show ppp multilink** - Zeigt Informationen zu aktiven Multilink-Paketen an. Verwenden Sie diesen Befehl, um die Multilink-Verbindung zu überprüfen.
- **show dialer [Schnittstellentyp]** - Zeigt allgemeine Diagnoseinformationen für DDR-konfigurierte Schnittstellen an. Wenn der Dialer richtig eingeschaltet wird, ist der `Status Dialer` die Meldung "Sicherungsschicht". Wenn eine `physische Ebene` angezeigt wird, wird impliziert, dass das Verbindungsprotokoll verfügbar war, das Network Control Protocol (NCP) jedoch nicht. Die Quell- und Zieladressen des Pakets, das das Wählen initiiert hat, werden in der Zeile `Wählgrund` angezeigt. Dieser **show**-Befehl zeigt auch die Konfiguration des Timers und die Zeit vor dem Timeout der Verbindung an.
- **Details zum Benutzernamen des Anrufers anzeigen** - zeigt Parameter für den jeweiligen Benutzer an, z. B. die zugewiesene IP-Adresse, PPP- und PPP-Paketparameter. Wenn Ihre Version der Cisco IOS-Software diesen Befehl nicht unterstützt, verwenden Sie den Befehl **show user**.
- **show dialer map** - Zeigt konfigurierte dynamische und statische Dialer-Karten an. Mit diesem Befehl können Sie überprüfen, ob eine dynamische Dialerzuordnung erstellt wird. Pakete können nur über eine Wählkarte weitergeleitet werden.

Beispielausgabe

Nachfolgend sind einige **show**-Befehlsausgaben für erfolgreiche Anrufe aufgeführt. Achten Sie auf die fett formatierten Abschnitte und die in der Ausgabe enthaltenen Kommentare. Vergleichen Sie die Ausgabe, die Sie erhalten, mit den hier gezeigten Ergebnissen.

Fehlerbehebung

Dieser Abschnitt enthält Informationen zur Fehlerbehebung in Ihrer Konfiguration.

Ressourcen zur Fehlerbehebung

Verwenden Sie diese Ressourcen je nach Bedarf:

- [Fehlerbehebung bei eingehenden Modemanrufen](#): Verwenden Sie dieses Dokument, um Fehler bei analogen Anrufen zu beheben.
- [PRI Async Modem Callin \(Async-Modem-Anruf\)](#): Verwenden Sie dieses Dokument für zusätzliche Informationen zur Fehlerbehebung bei Analoganruf-Ausfällen.
- [Fehlerbehebung bei eingehenden ISDN-Anrufen](#) - Verwenden Sie dieses Dokument, um Fehler bei ISDN-Anrufern zu beheben.
- [PRI ISDN Callin](#): Verwenden Sie dieses Dokument für zusätzliche Informationen zur Fehlerbehebung bei ISDN-Anrufausfällen.
- [T1 Troubleshooting Flow Chart](#) (Flussdiagramm zur Fehlerbehebung): Verwenden Sie dieses Flussdiagramm, wenn Sie vermuten, dass der T1-Schaltkreis nicht ordnungsgemäß funktioniert.
- [Loopback-Tests für T1/56K-Leitungen](#) - Verwenden Sie dieses Dokument, um zu überprüfen, ob der T1-Port des Routers ordnungsgemäß funktioniert.

Befehle zur Fehlerbehebung

Bestimmte **show**-Befehle werden vom [Output Interpreter Tool](#) unterstützt (nur [registrierte](#) Kunden), mit dem Sie eine Analyse der **show**-Befehlsausgabe anzeigen können.

Hinweis: Bevor Sie **Debugbefehle** ausgeben, lesen Sie [Wichtige Informationen über Debug-Befehle](#).

- **Debug Dialer** (Debug-Dialer): Zeigt Informationen zum DDR-Debuggen über die auf einer Dialer-Schnittstelle empfangenen Pakete an. Diese Informationen können helfen, sicherzustellen, dass es interessanten Datenverkehr, der die Dialer-Schnittstelle verwendet.
- **debug isdn q931** - zeigt die Einrichtung der Anrufe und das Beenden der ISDN-Netzwerkverbindung (Layer 3).
- **Debug-Modem**: Zeigt die Modemzeilenaktivität auf einem Zugriffsserver an. Die Ausgabe wird angezeigt, wenn die Modemleitung den Status ändert.
- **debug modem csm** - Ermöglicht Ihnen, CSM-Probleme (Call Switching Module) auf Routern mit internen digitalen Modems zu beheben. Mit diesem Befehl können Sie die gesamte Abfolge der Umschaltung von ein- und ausgehenden Anrufen verfolgen.
- **debug ppp negotiation**: Zeigt Informationen über den PPP-Datenverkehr und den Austausch an und handelt Link Control Protocol (LCP), Authentication und Network Control Protocol (NCP) aus. Eine erfolgreiche PPP-Aushandlung öffnet zuerst den LCP-Status, authentifiziert sich dann, und schließlich wird NCP ausgehandelt. Bei der LCP-Aushandlung werden mehrere Link-Parameter wie die Maximum Receive Reconstructed Unit (MRRU) festgelegt.
- **debug ppp authentication**: Zeigt Meldungen des PPP-Authentifizierungsprotokolls an, darunter CHAP-Paketaustausch und Passwort Authentication Protocol (PAP)-Austausch.
- **debug ppp error (ppp-Fehler debuggen)**: Zeigt Protokollfehler und Fehlerstatistiken an, die mit der Aushandlung und Ausführung von PPP-Verbindungen verknüpft sind.

Beispielausgabe für Debugging

Hier einige **Debug**-Ausgaben für erfolgreiche Aufrufe. Achten Sie auf die Fettschnitte und die Kommentare in den Ausgaben. Vergleichen Sie die Ausgabe, die Sie erhalten, mit dem hier gezeigten Ergebnis.

Für einen analogen Anruf
