[Zugehörige Informationen](#)

[Einführung](#)

Dieser technische Tipp erläutert, wie Zeitüberschreitungen pro Benutzer auf Cisco Access-Servern implementiert werden. Damit Timeouts pro Benutzer ordnungsgemäß funktionieren, müssen Sie Cisco IOS Version 11.3(8)T oder höher ausführen. Wenn Sie eine ältere Version von Cisco IOS ausführen, funktionieren die Timer möglicherweise nur in bestimmten Basiskonfigurationen, z. B. async, ohne virtuelle Profile.

Dieses Dokument behandelt die Konfiguration des Netzwerkzugriffsservers (NAS) und des AAA-Servers (Authentication, Authorization, Accounting). Außerdem werden **show** and **debug**-Befehlsausgaben bereitgestellt, sodass Sie überprüfen können, ob die Geräte ordnungsgemäß funktionieren, und Probleme damit beheben können.

[Voraussetzungen](#)

[Anforderungen](#)

Für dieses Dokument bestehen keine speziellen Anforderungen.

Verwendete Komponenten

Die Informationen in diesem Dokument basieren auf den folgenden Software- und Hardwareversionen:

- Cisco IOS Version 11.3(8)T oder höher

Die Informationen in diesem Dokument wurden von den Geräten in einer bestimmten Laborumgebung erstellt. Alle in diesem Dokument verwendeten Geräte haben mit einer leeren (Standard-)Konfiguration begonnen. Wenn Ihr Netzwerk in Betrieb ist, stellen Sie sicher, dass Sie die potenziellen Auswirkungen eines Befehls verstehen.

Konventionen

Weitere Informationen zu Dokumentkonventionen finden Sie unter [Cisco Technical Tips Conventions](#).

Technische Details

Bevor Sie Timeouts pro Benutzer diskutieren, die andere Variablen wie AAA-Konfiguration und RADIUS/TACACS+-Server enthalten, werden wir untersuchen, wie ein Zugriffsserver für feste Zeitüberschreitungen konfiguriert wird. Dies sind Zeitüberschreitungen, die global angewendet werden und auf alle Benutzer angewendet werden, die sich einwählen.

Die wichtigsten Cisco IOS-Befehle sind **Dialer-Timeout (Leerlaufzeitüberschreitung)** und **Timeout (absolute Zeitüberschreitung)**. Beide sind Schnittstellenkonfigurationsbefehle. Außerdem wird ein dritter Befehl, **ppp timeout idle**, erläutert, der auf Zugriffs-Schnittstellen verwendet wird.

Leerlaufzeitüberschreitung beim Wähler <x>

Dieser Befehl kann auf jeder Dialer-fähigen Schnittstelle konfiguriert werden und bestimmt, wie lange die Verbindung vor dem Beenden nicht aktiv sein kann (in Sekunden). Nachstehend sind vier Punkte aufgeführt, die Sie über diesen Befehl beachten sollten:

1. Dieser Befehl kann nur auf Schnittstellen angewendet werden, die dialer-fähig sind. Standardmäßig sind alle ISDN-Schnittstellen (BRI und PRI) dialer-fähig, daher ist das Hinzufügen dieses Befehls kein Problem. Async-Schnittstellen (einschließlich Gruppen-Async-Schnittstellen) sind standardmäßig nicht dialer-fähig. Sie müssen sie durch Eingabe des Befehls **Dialer in Band** vornehmen. Erst nach Eingabe des **In-Band-Befehls des Dialers** auf der asynchronen Schnittstelle können Sie **Leerlaufzeitüberschreitungen** konfigurieren. **Hinweis**: Die Vorlage (und damit die Zugriffsschnittstellen) sind nicht wählerfähig (sie sind nur Punkt-zu-Punkt) und können daher diesen Befehl nicht verwenden.
2. Auf einer Dialer-fähigen Schnittstelle (ISDN oder async mit Dialer-In-Band) ist die Standardeinstellung **Dialer Inaktivität 120** (Sekunden). Dies ist in einer ISP-Umgebung im Allgemeinen zu kurz, daher sollten Sie dies fast immer erhöhen.
3. Die **Leerlaufzeitüberschreitung** wird standardmäßig nur für ausgehenden Datenverkehr (Datenverkehr zum Benutzer) zurückgesetzt, der mit der Wählliste übereinstimmt (d. h., sie wird als interessant angesehen). Es ist auch möglich, das Schlüsselwort für eingehenden

interessanten Datenverkehr zurückzusetzen, indem Sie das **entsprechende** Schlüsselwort am Ende des Befehls hinzufügen (d. h. **Dialer Inaktivität-Zeitüberschreitung 600**).

4. Datenverkehr, der als "interessant" eingestuft wird, wird durch den **Wählerlisten-Befehl <n>** definiert, der <n> der Nummer in der **Wählergruppe <n>** entspricht.

timeout absolute <x> <y>

Dieser Befehl kann auf jeder WAN-Schnittstelle konfiguriert werden, einschließlich asynchroner Schnittstellen, ISDN-Schnittstellen, Dialer-Schnittstellen und Vorlagenschnittstellen. Sie steuert, wie lange die Verbindung vor dem Beenden verfügbar sein kann. Beachten Sie, dass die Syntax <x> <y> in Minuten und <y> in **Sekunden** liegt.

ppp timeout idle <x>

Dieser Befehl kann nur auf Vorlagenschnittstellen konfiguriert werden (und ist sogar im Parser verborgen) und steuert, wie lange die Verbindung vor dem Beenden (in Sekunden) inaktiv sein kann. Seine Funktion ist sehr ähnlich wie die des Befehls **Dialer Leerlauf-Timeout** an Dialer-Schnittstellen, nur **ppp timeout idle** ist für vtemplate/vaccess-Schnittstellen. Da dieser Befehl speziell für vTemplate/vAccess-Schnittstellen verwendet wird, eignet er sich für Virtual-Profile-Konfigurationen (bei denen immer eine Zugriffsschnittstelle für einen Benutzer erstellt wird) und für Virtual Private Dial-up-Netzwerk (VPDN)-Home-Gateways (bei denen die geplanten Schnittstellen immer auf einer Zugriffsebene terminiert werden). Im Gegensatz zum Befehl **dialer idle-timeout** gibt es kein Konzept für interessanten Datenverkehr, sodass der gesamte Benutzerdatenverkehr den Timer für Leerlaufzeiten zurücksetzt. Nicht benutzerdefinierter Datenverkehr wie LCP-Keepalives (Link Control Protocol) und NCP-Verhandlungspakete (Network Control Protocol) setzen den Timer nicht zurück.

Konfigurieren

In diesem Abschnitt erhalten Sie Informationen zum Konfigurieren der in diesem Dokument beschriebenen Funktionen.

Hinweis: Um weitere Informationen zu den in diesem Dokument verwendeten Befehlen zu erhalten, verwenden Sie das [Command Lookup Tool](#) ([nur registrierte](#) Kunden).

In diesem Dokument werden folgende Konfigurationen verwendet:

- [Basiskonfiguration \(virtuelle Profile nicht aktiviert\)](#)
- [Globale Zeitüberschreitungen](#)
- [Timeouts pro Benutzer - AAA-Serverkonfiguration](#)
- [Timeouts pro Benutzer - NAS-Konfiguration](#)

Basiskonfiguration (virtuelle Profile nicht aktiviert)

Zu Lernzwecken wird eine Basiskonfiguration wie die unten gezeigte angenommen. Die Funktion für virtuelle Profile ist nicht aktiviert.

exec-timeout 60 0 ! end
```

Globale Zeitüberschreitungen

Im nächsten Beispiel wird ein Timeout für Leerlaufzeiten von 30 Minuten (1800 Sekunden) und drei Stunden (180 Minuten) für Benutzer festgelegt. Die Delta-Konfigurationsänderung, die **globale PoP-Timeouts** ermöglicht, ist wie folgt:

```
interface Serial0:23
 dialer idle-timeout 1800
 timeout absolute 180
!
! interface Group=Async1 dialer in-band dialer idle-timeout 1800 dialer-group 1 timeout absolute
180
```

Wenn Sie keine Dialer-Liste 1 haben, müssen Sie eine angeben. Die einfachste wäre die **Wählerliste 1 Protokoll-IP-Genehmigung**.

Wenn Sie virtuelle Profile verwenden, kann die Konfiguration einfacher sein, da Sie die Zeitüberschreitung einfach auf die **Virtual-Template-Schnittstelle** einstellen können, wie unten gezeigt:

```
interface Virtual-Template1
 ppp timeout idle 1800
 timeout absolute 180
```

Timeouts pro Benutzer - AAA-Serverkonfiguration

Nachdem wir an globalen Zeitüberschreitungen gearbeitet haben, werden wir dieses Wissen auf Zeitüberschreitungen pro Benutzer erweitern. Die Werte für die Timer pro Benutzer werden während der Netzwerkautorisierung heruntergefahren. Daher muss der Befehl **aaa authorized network** (Autorisierungsnetzwerk für alle verwendeten Methoden, RADIUS oder TACACS+, konfiguriert sein. Beachten Sie außerdem, dass Timer pro Benutzer immer alle globalen Werte überschreiben, die auf dem NAS vorkonfiguriert sind. Die Funktionsweise der Timer pro Benutzer besteht darin, dass der Zugriffsserver, wenn er die Timeout-Attribute während der Netzwerkautorisierungsphase erhält, diese Attribute in eine Reihe von Konfigurationsbefehlen übersetzt, die in die Schnittstelle eingegeben werden, mit der der Benutzer verbunden wird. Diese Konfigurationsbefehle, die von einem Hintergrundprozess in die Schnittstelle eingegeben werden, sind temporär. Sie werden entfernt, wenn der Benutzer die Verbindung trennt.

Im Folgenden sind einige Beispielbenutzerprofile auf dem Server aufgeführt:

RADIUS-Profil

```
timeout-absolute-ppp Password = "cisco"
 Service-Type = Framed,
 Framed-Protocol = PPP,
```

```
Framed-IP-Address = 255.255.255.254,  
Session-Timeout = 600
```

```
timeout-idle-ppp Password = "cisco"  
Service-Type = Framed,  
Framed-Protocol = PPP  
Framed-IP-Address = 255.255.255.254,  
Idle-Timeout = 300
```

```
timeout-both-ppp Password = "cisco"  
Service-Type = Framed,  
Framed-Protocol = PPP,  
Framed-IP-Address = 255.255.255.254,  
Session-Timeout = 600,  
Idle-Timeout = 300
```

Hinweis: Die Syntax kann je nach Einrichtung des Wörterbuchs variieren.

TACACS+-Profile

```
user = timeout-absolute-ppp {  
    chap = cleartext cisco  
    service = ppp protocol = lcp {  
        timeout = 10  
    }  
    service = ppp protocol = ip {  
        addr-pool = "default"  
    }  
}
```

```
user = timeout-idle-ppp {  
    chap = cleartext cisco  
    service = ppp protocol = lcp {  
        idletime = 5  
    }  
    service = ppp protocol = ip {  
        addr-pool = "default"  
    }  
}
```

```
user = timeout-both-ppp {  
    chap = cleartext cisco  
    service = ppp protocol = lcp {  
        timeout = 10  
        idletime = 5  
    }  
    service = ppp protocol = multilink { }  
    service = ppp protocol = ip {  
        addr-pool = "default"  
    }  
}
```

[Timeouts pro Benutzer - NAS-Konfiguration](#)

Wenn Sie nur async (kein ISDN) betreiben und keine virtuellen Profile verwenden, solange Sie auf den asynchronen Schnittstellen (oder Gruppen-Async-Schnittstellen) **Dialer-In-Band** konfiguriert haben, sollten die Timer pro Benutzer funktionieren. Beim Hintergrundprozess werden die Timer an die async-Schnittstelle eingefügt. Dabei werden die **Befehle** für **Leerlaufzeitüberschreitung** und **absolute Zeitüberschreitung** mit den von RADIUS/TACACS+ übergebenen Werten verwendet, und diese werden entfernt, wenn der Benutzer die Verbindung trennt.

Wenn Sie nur async (kein ISDN) betreiben und virtuelle Profile verwenden, benötigen Sie keinen **Dialer in-band**, der auf der asynchronen (oder Gruppen-Async)-Schnittstelle konfiguriert ist. Es sollte einfach funktionieren. Beim Hintergrundprozess werden die Timer an die Zugriffsoberfläche eingefügt. Dabei werden die **Befehle** für das **Leerlauf-Timeout** und das **absolute Timeout** mit den von RADIUS/TACACS+ übergebenen Werten verwendet, und diese werden entfernt, wenn der Benutzer die Verbindung trennt.

Wenn Sie ISDN-Benutzer haben und Timer pro Benutzer erstellen müssen, müssen Sie möglicherweise virtuelle Profile verwenden. Der Grund hierfür ist, dass der von uns vorhin beschriebene Hintergrundprozess für ISDN-Schnittstellen nicht funktioniert. Das heißt, Sie können den B-Kanal nicht konfigurieren, mit dem der Benutzer verbunden ist. Sie können nur den D-Channel konfigurieren, der alle betrifft. Wenn ein Benutzer jedoch Multilink für eine Sitzung aushandelt, erstellt der Access-Server automatisch eine Virtual-Access-Schnittstelle, die als Paketschnittstelle für den Benutzer fungiert. Der Hintergrundprozess funktioniert auf virtuellen Zugriffsschnittstellen, funktioniert aber nicht bei einem Nicht-Multilink-ISDN-Anruf, bei dem keine virtuelle Zugriffsschnittstelle vorhanden ist. Wenn Sie also einzelne B-Channel-Benutzer haben, die keine Multilink-Aushandlungen aushandeln und für diese Zeitüberschreitungen pro Benutzer installieren möchten, müssen Sie virtuelle Profile aktivieren. Die Aktivierung virtueller Profile erfordert die Erstellung einer Zugriffsschnittstelle für alle Benutzer (nicht nur für die Multilink-Benutzer). Der Hintergrundprozess kann die **ppp timeout idle** und **timeout absolute** Befehle erfolgreich einfügen. Wenn Sie virtuelle Profile nicht aktivieren, können async-Benutzer und Multilink-ISDN-Benutzer Timeouts pro Benutzer zuweisen. Nicht-Multilink-ISDN-Benutzern können jedoch keine Timeouts pro Benutzer zugewiesen werden. Es gelten nur die globalen Timeouts, die statisch auf der Schnittstelle konfiguriert sind (falls vorhanden). Wenn Sie versuchen, Timeouts pro Benutzer auf einen Nicht-Multilink-ISDN-Benutzer anzuwenden, ohne dass die virtuellen Profile aktiviert sind, schlägt die Benutzerverbindung die Autorisierung fehl, da der Zugriffsserver die obligatorischen Timeout-Attribute pro Benutzer nicht verarbeiten konnte.

Darüber hinaus wurde Cisco IOS 11.3(8.1)T und Folgeversionen eine Funktion hinzugefügt, mit der benutzerspezifische Timeouts auf Nicht-Multilink-ISDN-Benutzer angewendet werden können. Dabei wird im Wesentlichen der in der Regel verwendete Hintergrundprozess-Konfigurationsmodus umgangen und die Timer direkt auf den B-Kanal eingestellt, ohne die Befehlszeilenschnittstelle zu verwenden.

Diese komplizierte Konfiguration lässt sich anhand der folgenden zwei Regeln zusammenfassen:

- Wenn Sie keine virtuellen Profile verwenden, konfigurieren Sie den **Dialer-In-Band** auf den asynchronen Schnittstellen, und führen Sie Cisco IOS 11.3(8.1)T oder höher aus. Wenn Sie Cisco IOS 11.3(8)T verwenden, achten Sie darauf, dass für ISDN-Benutzer, die nicht mehrere Verbindungen verwenden, keine Timeouts pro Benutzer angewendet werden können. Andernfalls wird die Verbindung nicht hergestellt.
- Wenn virtuelle Profile verwendet werden, funktioniert Cisco IOS 11.3(8)T oder höher gut.

Überprüfen

Für diese Konfiguration ist derzeit kein Überprüfungsverfahren verfügbar.

Fehlerbehebung

Dieser Abschnitt enthält Informationen zur Fehlerbehebung in Ihrer Konfiguration. Zum Debuggen

sind sechs Beispiele für die Ausgabe von Aufrufen enthalten. Um direkt zu einem bestimmten Abschnitt zu springen, wählen Sie einen der folgenden Links:

Bestimmte **show**-Befehle werden vom [Output Interpreter Tool](#) unterstützt (nur [registrierte](#) Kunden), mit dem Sie eine Analyse der **show**-Befehlsausgabe anzeigen können.

Hinweis: Bevor Sie **Debugbefehle** ausgeben, lesen Sie [Wichtige Informationen über Debug-Befehle](#).

- [Async Call with Virtual Profiles \(Async-Anruf mit virtuellen Profilen\) - Verbindung wird nicht deaktiviert](#)
- [Async Call with Virtual Profiles - Connection Idds Out](#)
- [Async Call ohne virtuelle Profile](#)
- [Multilink Single-Channel-ISDN-Anruf ohne virtuelle Profile](#)
- [Nicht-Multilink Single-Channel-ISDN-Anruf ohne virtuelle Profile](#)
- [Nicht-Multilink Single-Channel-ISDN-Anruf mit virtuellen Profilen](#)

Hinweis: Um die gleichen Befehle und Ausgaben anzuzeigen, die unten dargestellt werden, müssen Sie Cisco IOS Version 11.3AA oder Version 12.0T ausführen.

[Async Call with Virtual Profiles \(Async-Anruf mit virtuellen Profilen\) - Verbindung wird nicht deaktiviert](#)

Unten sehen Sie einen asynchronen Anruf mit virtuellen Profilen. Das Profil installiert ein absolutes Timeout von 90 Sekunden und ein Timeout bei Leerlaufzeiten von 60 Sekunden. In diesem Beispiel wird die Verbindung nicht deaktiviert. Weitere Einzelheiten finden Sie in den Kommentaren in der unten stehenden Ausgabe. Kommentare sind hervorgehoben und in kursiver Schrift dargestellt.

Async Call ohne virtuelle Profile

Unten sehen Sie einen asynchronen Anruf ohne Aktivierung virtueller Profile. Beachten Sie, dass der Befehl **dialer idle-timeout** anstelle des Befehls **ppp timeout idle** verwendet wird, da keine virtuellen Profile verwendet werden und keine Zugriffsoberfläche vorhanden ist. Außerdem sehen Sie, wie der Befehl **Timeout pro Benutzer** und die **no-Version** der Befehle erstellt werden. Die **Timer-Befehle für jeden Benutzer** werden sofort installiert, während die Befehlsversion **no** in die Schnittstelle eingebunden wird, die verarbeitet wird, wenn der Benutzer die Verbindung trennt.

[Nicht-Multilink Single-Channel-ISDN-Anruf ohne virtuelle Profile](#)

Unten sehen Sie einen Nicht-Multilink-ISDN-Anruf mit einem Kanal ohne Aktivierung virtueller Profile. In diesem Beispiel wird Cisco IOS 11.3(8.2)AA ausgeführt, damit diese Timer korrekt installiert werden können. Beachten Sie jedoch, dass dazu keine Konfigurationsbefehle erstellt wurden. Die Timer wurden intern im Code festgelegt.
