Introduction

This document describes how to configure SSH server with use of x509v3 certificates on IOS devices in accordance with standard RFC6187.

The Secure Shell Protocol (SSH) provides mutual authentication, i.e. both client and server are authenticated. Traditionally, the server uses the RSA private and public keypair for authentication. The SSH client computes the checksum of public key and asks the administrator if it is trusted. The administrator should export the public key from router with use of out-of-band method and compare the values. In practice, this is a cumbersome method and often the public key is accepted without verification, which leads to potential risk of man-in-the-middle attacks. RFC6187 standard is a solution to this concern as it provides similar level of security and user experience to the TLS (Transport Layer Security) protocol commonly used to protect web-based transmissions.

Prerequisites

Requirements

Cisco recommends that you have knowledge of these topics:

- PKI infrastructure

Components Used

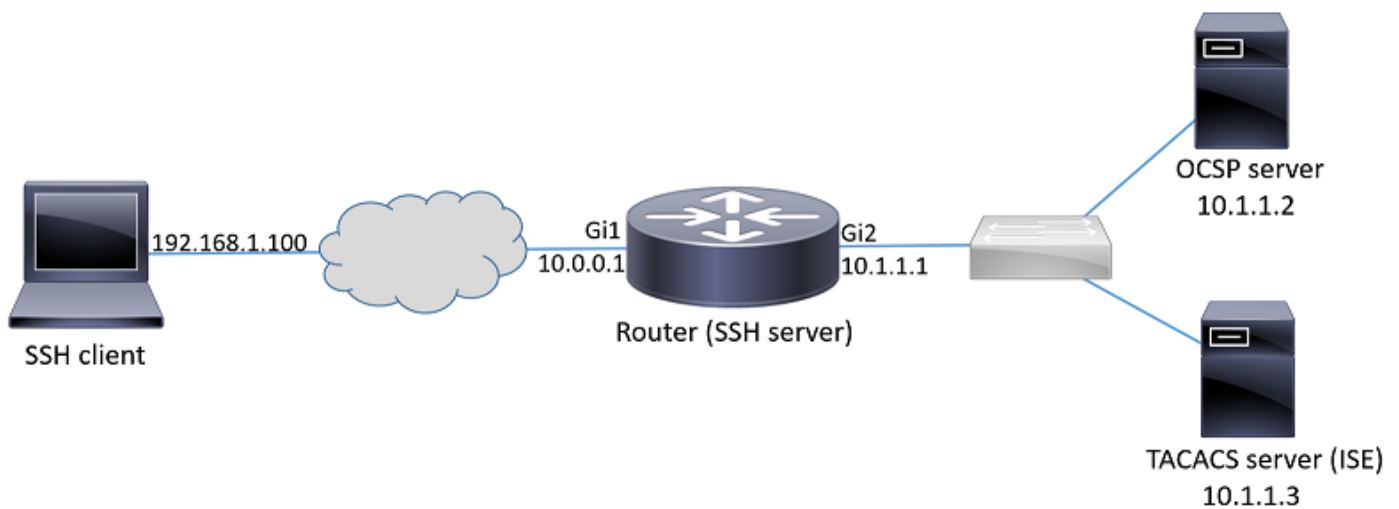

The information in this document is based on these software and hardware versions:

- CSR 1000v router running IOS-XE version 16.6.1
- Pragma Fortress SSH client
- Windows Server 2016 OCSP server
- Identity Services Engine version 2.1

The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, ensure that you understand the potential impact of any command.

Configure

Network Diagram

Deployment considerations

- An RFC6187-compatible SSH client is necessary to take advantage of the feature.
- The feature has been implemented in IOS version 15.5(2)T and IOS-XE version 15.5(2)S.
- The SSH client and server negotiates supported authentication mechanisms. All of the authentication mechanisms previously supported on the device may continue to run concurrently with x509-based authentication mechanisms in order to ensure smooth transition.
- Administrator may choose to use x509-based authentication method for server only, client only or both.
- The IOS server can verify if the certificate presented by the client is not revoked. In order to do that, the database of revoked certificates is consulted upon each connection. This allows for revocation of access without the need to reconfigure other devices, in case, if the private key of the certificate is compromised or if access for a specific user needs to be revoked.
- Revocation check is optional, but it is highly recommended to have the possibility to

deny access based on compromised credentials. Another option is to perform authorization for the username fetched from certificate on the external Terminal Access Controller Access-Control System (TACACS) or RADIUS server. In case the certificate is compromised, the account can be disabled on the external server to prevent access with use of that certificate.

- The authorization of users can be performed by external server or it can be skipped (all users with a valid certificate assumed to have privileges to access device). The former method is used in this example for simplicity.
- In order to successfully verify the authentication data of the other party, the client and server only need to trust a common Certificate Authority (CA). This means that only the certificate of CA that signed the router certificate needs to be installed on the client device trusted certificate store.
- The certificate provides information about identity of the other party (Common Name and Subject Alternative Name are typically used for that purpose). The client should compare the hostname or IP address name of the server that was provided as input by the administrator with the identity data available in the presented certificate. It severely limits the opportunities of man-in-the-middle or other impersonation attacks.

Configurations

Configure AAA parameters. In a basic scenario (without external authorization server), the authorization for the username fetched from certificate can be skipped.

```
aaa new-model
aaa authorization network CERT none
```

Configure a trustpoint that holds the CA certificate and optionally the router certificate.

```
crypto pki trustpoint SSH
enrollment mode ra
enrollment url http://10.1.1.2:80/CertSrv/mscep/mscep.dll
serial-number
ip-address 10.0.0.1
subject-name cn=10.0.0.1
revocation-check ocp
ocsp url http://10.1.1.2/ocsp
rsa-keypair SSH 2048
authorization list CERT
! The username has to be fetched from the certificate for accounting and authorization purposes.
Multiple options are available.
authorization username subjectname commonname
```

Tip: In case OCSP server is unreachable, the administrator may choose to disallow all access by using **revocation-check ocp** configuration or allow access without revocation check using **revocation-check ocp none** (not recommended).

Configure allowed authentication mechanisms used during SSH tunnel negotiation.

```
! Algorithms used to authenticate server
ip ssh server algorithm hostkey x509v3-ssh-rsa ssh-rsa

! Acceptable algorithms used to authenticate the client
ip ssh server algorithm authentication publickey password keyboard

! Acceptable pubkey-based algorithms used to authenticate the client
ip ssh server algorithm publickey x509v3-ssh-rsa ssh-rsa
```

Configure the SSH server to use correct certificates in the authentication process.

```
ip ssh server certificate profile
! Certificate used by server
server
trustpoint sign SSH

! CA used to authenticate client certificates
user
trustpoint verify SSH
```

(Optional) Integration with TACACS Server

After the username is fetched from the certificate, the IOS can perform authorization for that username against TACACS server. This is especially useful if the TACACS server is already deployed for device administration.

Note: The IOS SSH server currently does not support authentication method chaining. This means that if the certificates are used to authenticate the user, the TACACS server cannot be used for password authentication. It can only be used for authorization.

Configure TACACS server.

```
tacacs server ISE
address ipv4 10.1.1.3
key cisco123
```

Configure the authorization list to use the TACACS server.

```
aaa authorization network ISE group tacacs+
```

1. Configure ISE (Identity Services Engine). Configuration example can be found at:

<https://www.cisco.com/c/en/us/support/docs/security/identity-services-engine/200208-Configure-ISE-2-0-IOS-TACACS-Authentic.html>

2. Configure TACACS profile. Additional parameter **cert-application=all** needs to be configured in order for the authorization to succeed, navigate to **Work Centers > Device Administration > Policy Elements > Results > TACACS profiles > Add**.

Common Tasks

Common Task Type

<input checked="" type="checkbox"/> Default Privilege	<input type="text" value="15"/>	(Select 0 to 15)
<input checked="" type="checkbox"/> Maximum Privilege	<input type="text" value="15"/>	(Select 0 to 15)
<input type="checkbox"/> Access Control List	<input type="text"/>	
<input type="checkbox"/> Auto Command	<input type="text"/>	
<input type="checkbox"/> No Escape	<input type="text"/>	(Select true or false)
<input type="checkbox"/> Timeout	<input type="text"/>	Minutes (0-9999)
<input type="checkbox"/> Idle Time	<input type="text"/>	Minutes (0-9999)

Custom Attributes

[+ Add](#) [Trash](#) [Edit](#)

<input type="checkbox"/>	Type	Name	Value
<input type="checkbox"/>	MANDATORY	cert-application	all

3. In order to configure policy set, navigate to **Work Centers > Device Administration > Device Admin Policy Sets > Add**.

Authentication Policy

Default Rule (If no match) : Allow Protocols : Default Device Admin and use : All_User_ID_Stores

Authorization Policy

Exceptions (1)

Local Exceptions

Status	Rule Name	Conditions (identity groups and other conditions)	Command Sets	Shell Profiles
<input checked="" type="checkbox"/>	Certificate auth	if network admins	then <i>Select Profile(s)</i>	permit_lvl_15

Verify

```
show ip ssh
SSH Enabled - version 1.99
Authentication methods:publickey,password,keyboard-interactive
Authentication Publickey Algorithms:x509v3-ssh-rsa,ssh-rsa
```

```
Hostkey Algorithms:x509v3-ssh-rsa,ssh-rsa
--- output truncated ----
```

```
show users
```

```
Line User Host(s) Idle Location
1 vty 0 admin1 idle 00:02:37 192.168.1.100
```

Troubleshoot

These debugs are used to track successful session:

```
debug ip ssh detail
debug crypto pki transactions
debug crypto pki messages
debug crypto pki validation
```

```
