Introduction

This document provides a sample configuration for the configuration of multiple Originating Point Codes (OPCs) on a Cisco PGW 2200 Softswitch.

Prerequisites

Requirements

Before you attempt this configuration, ensure that you meet these requirements:

- Cisco Media Gateway Controllers
- Cisco Signalling Link Terminals (SLT)
- SS7 Signalling

Components Used

The information in this document is based on these software and hardware versions:

- Cisco Media Gateway Controller – Cisco PGW 2200 Software Release 9.3(2)
- Cisco SLT on Cisco IOS® Software Release 12.2(15)T or later

The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, make sure that you understand the potential impact of any command.

Related Products

This configuration can also be used with these hardware and software versions:

- Cisco PGW 2200 Release 9.2(2)
- Cisco PGW 2200 Release 9.4(1)

Conventions

For more information on document conventions, refer to Cisco Technical Tips Conventions.

Background Information

A Cisco PGW 2200 can support up to six True OPCs. However, there are some configuration steps you must follow in order to deploy this configuration. Each OPC is bound to a single SS7 Input Output Channel Controller (IOCC) instance within the PGW 2200 where each IOCC is bound to a unique UDP port. Each unique port is identified when you configure the SESSIONSET that is used by the C7IPLNK in the PGW 2200 configuration. One problem that arises when you configure multiple OPCs is that linksets cannot be shared between IOCCs. As a result, you need to configure multiple entries for your adjacent point codes (APCs) with unique MML names. This allows you to have a unique entry to associate with the LNKSET for each IOCC.

The Cisco SLT functions as an SS7 front-end processor for the Cisco PGW 2200 node. The Cisco SLT is responsible for terminating the Message Transfer Part Level 1 (MTP1) and MTP2 layers of the SS7 protocol stack. The Cisco SLT transports the upper layers of the SS7 signaling (MTP3 and later) to and from the PGW 2200 over an IP network that uses Reliable User Datagram Protocol (RUDP). Prior to Cisco IOS Software Release 12.2(15)T, the SLT was only capable of having a single Active RUDP session between itself and the PGW 2200. The result was that you had to have a different SLT for each IOCC or OPC configured. This limitation was removed with the introduction of Cisco IOS Software Release 12.2(15)T which can now have active RUDP sessions with up to four IOCC's (see Note).

Note: The Cisco 2611XM SLT can only create two RUDP sessions to a Cisco PGW 2200 as opposed to four on the 2651XM, AS5350, or AS5400.

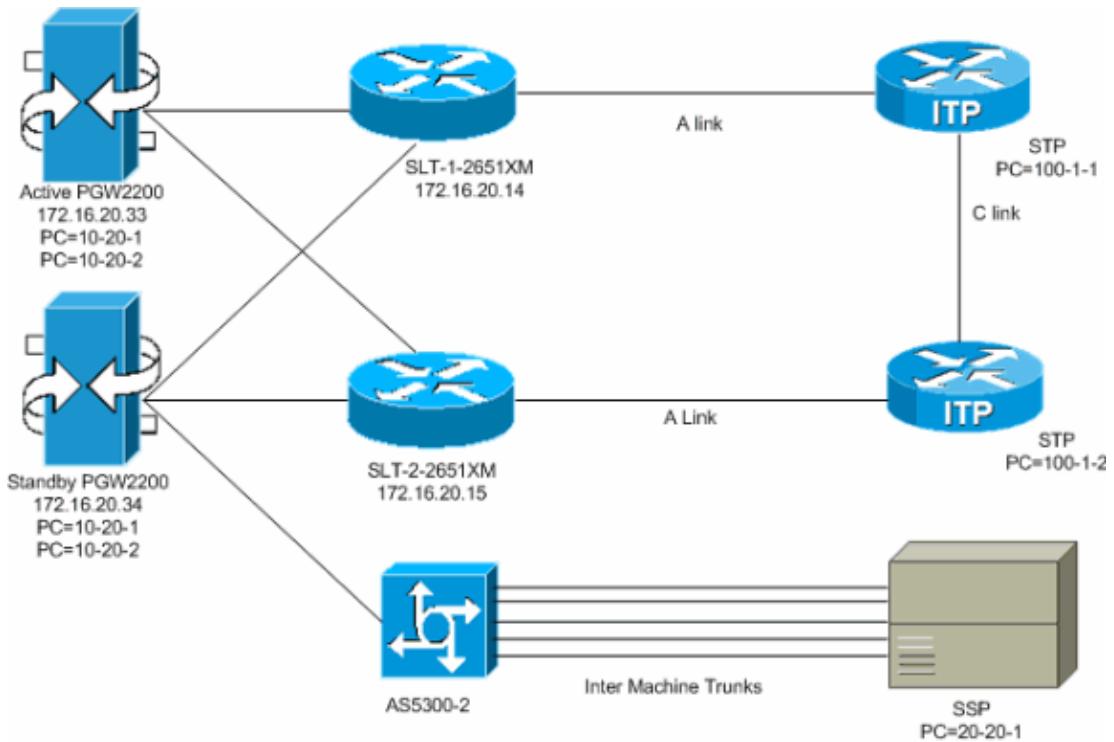

Configure

In this section, you are presented with the information to configure the features described in this document.

Note: To find additional information on the commands used in this document, use the Command Lookup Tool (registered customers only) .

Network Diagram

This document uses this network setup:

Configurations

This document uses these configurations:

- Active PGW 2200 (exported config.mml)
- SLT-1-2651XM (Cisco IOS)

Active PGW 2200 (exported config.mml)

```
!--- Two unique point codes are defined for the PGW 2200.

prov-add:OPC:NAME="opc-1",DESC="Originating Point Code 1",

Verify

From the PGW 2200, verify that all SS7 links are up and in service. This output represents some commands that you can run on the PGW 2200 that provide the status of various components of the configuration.
