Introduction

This document describes how to configure and troubleshoot external web-authentication (EWA) on a Catalyst 9800 Wireless LAN Controller (WLC).

Prerequisites

This document assumes that web server is properly configured to allow external communication and web page is properly configured to send all the necessary parameters for the WLC to authenticate the user and move client sessions to RUN state.

 **Note:** Since external resource access is restricted by the WLC through access-list permissions, all the scripts, fonts, images, and so on. that are used in the web-page need to be downloaded and remain local to the web server.

Necessary parameters for user authentication are:

- **buttonClicked:** This parameter needs to be set to value "4" for the WLC to detect the action as an authentication attempt.
- **redirectUrl:** The value in this parameter is used by the controller to direct the client to a specific website upon successful authentication.
- **err_flag:** This parameter is used to indicate some error such as incomplete information or incorrect credentials, on successful authentications it is set to "0".
- **username:** This parameter is only used for webauth parameter maps, if parameter map is set to consent then it can be ignored. It must be filled with the wireless client username.
- **password:** This parameter is only used for webauth parameter maps, if parameter map is set to consent then it can be ignored. It must be filled with the wireless client password.

Requirements

Cisco recommends that you have knowledge of these topics:

- Hyper Text Markup Language (HTML) web development
- Cisco IOS®-XE wireless features
- Web browser developer tools

Components Used

The information in this document is based on these software and hardware versions:

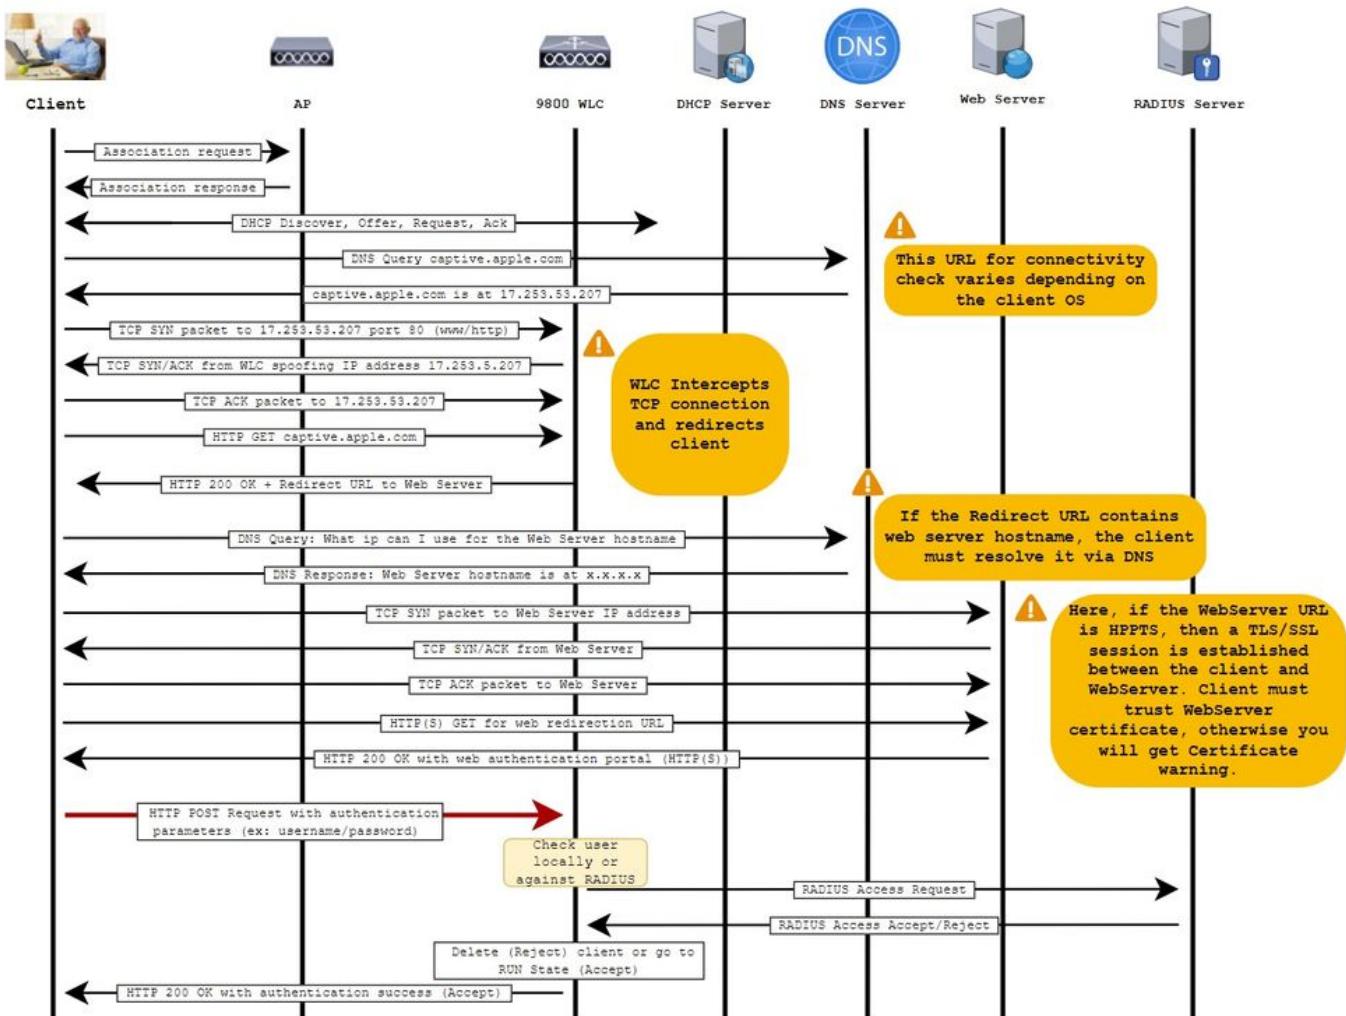

- C9800-CL WLC Cisco IOS®-XE Version 17.3.3
- Microsoft Windows Server 2012 with Internet Information Services (IIS) capabilities
- 2802 and 9117 Access Points

The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, ensure that you understand the potential impact of any command.

Background Information

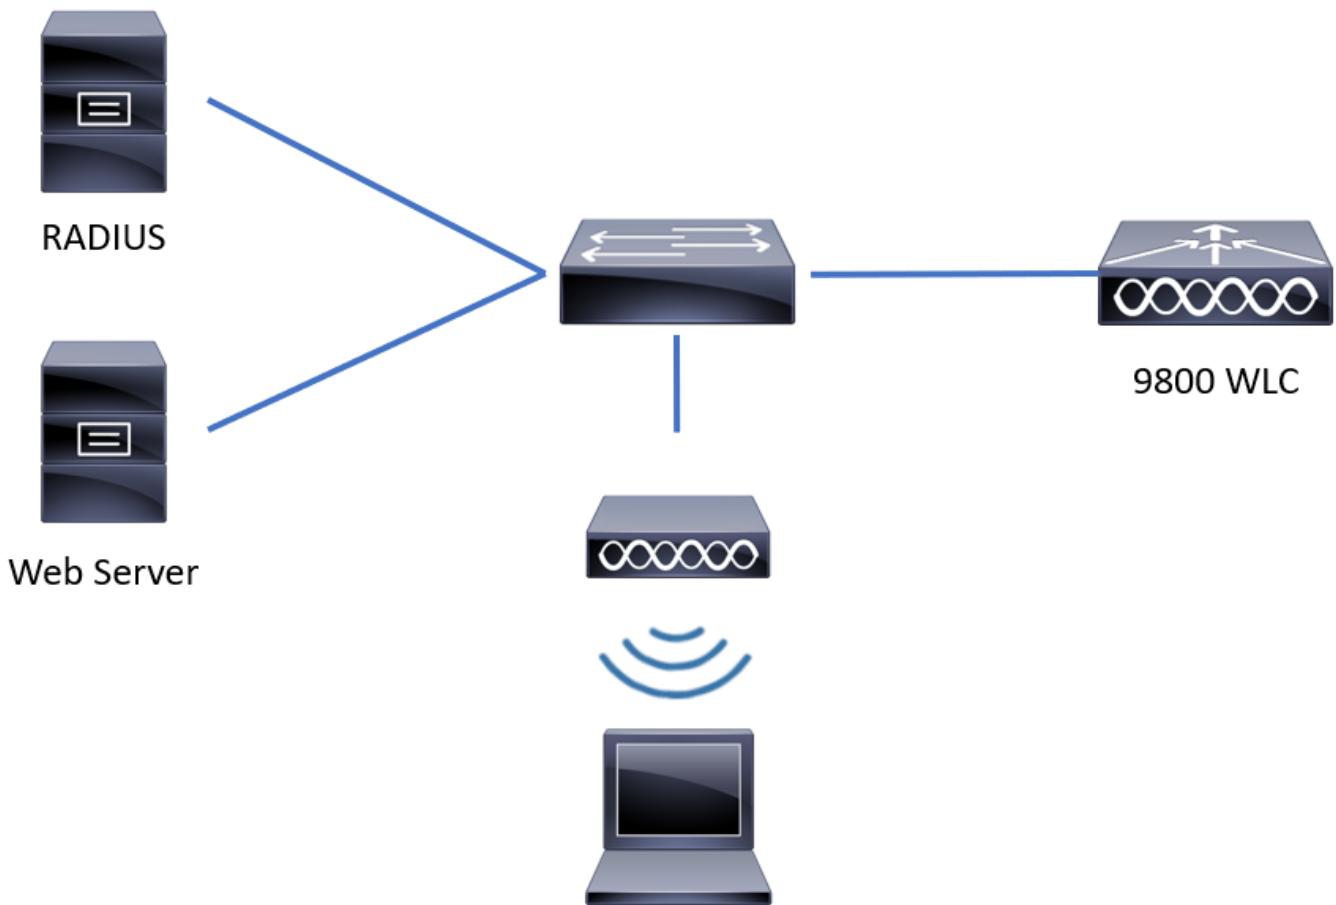

External web authentication leverages a web portal hosted outside of WLC on a dedicated web server or multi-purpose servers like Identity Services Engine (ISE) that allow granular access and management of web components. The handshake involved to successfully onboard a client to an external web authentication WLAN is rendered in the image. The image lists sequential interactions between wireless client, WLC, Domain Name system (DNS) server that resolves Uniform Resource Location (URL) and Webserver where WLC validates user credentials locally. This workflow is helpful to troubleshoot any failure conditions.

 **Note:** Before HTTP POST call from client to WLC, if secure web-authentication is enabled in the parameter-map and if the WLC does not have a trustpoint signed by a trusted Certification Authority, then a security alert is displayed in the browser. The client needs to bypass this warning and accept form re-submission in order for the controller to place client sessions in RUN state.

Configure

Network Diagram

Configure Web Parameter Settings

Step 1. Navigate to **Configuration > Security > Web Auth** and choose the global parameter map. Verify that **Virtual IPv4 Address** and **Trustpoint** are configured in order to provide proper redirection capabilities.

Note: By default, browsers use an HTTP website to initiate redirection process, if HTTPS redirection is needed then **Web Auth intercept HTTPs** has to be checked; this configuration is not recommended, however, as it increases CPU usage.

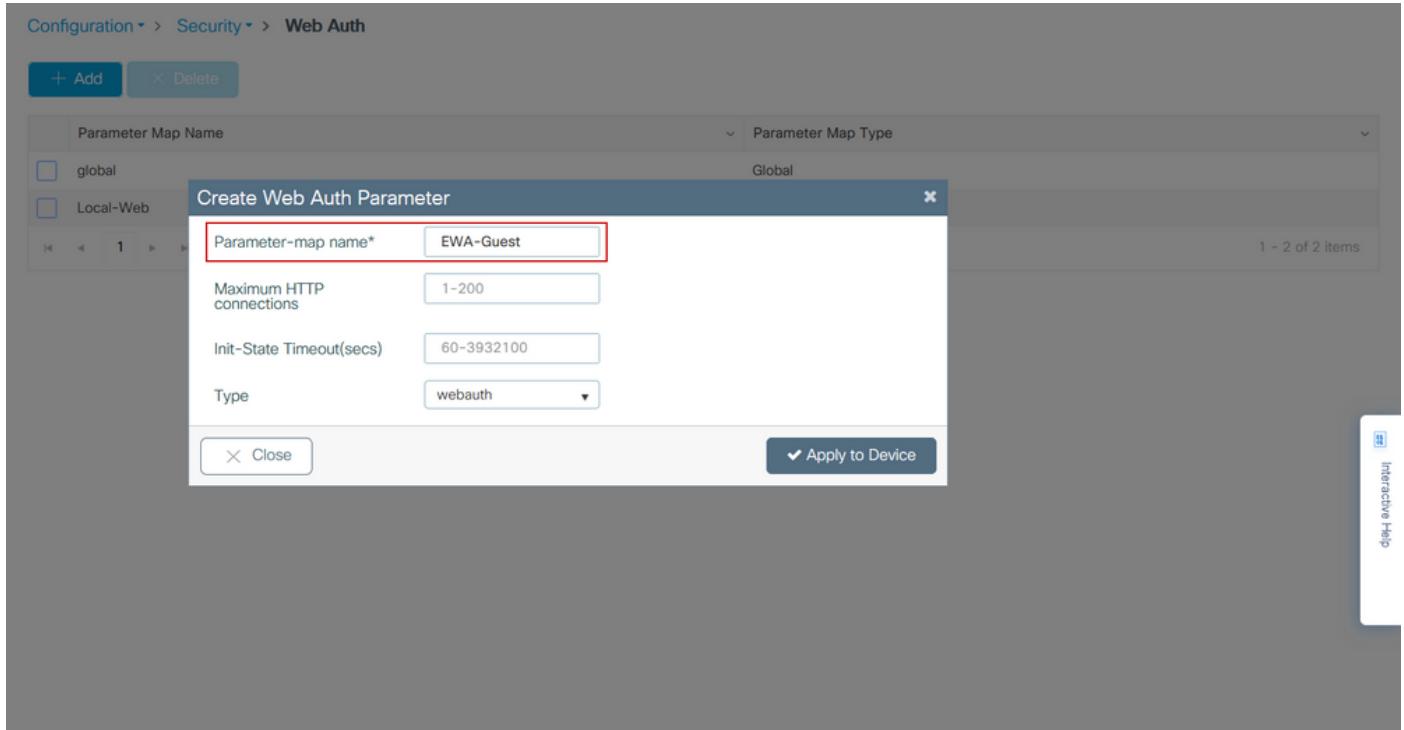

CLI configuration:

```
<#root>
9800#
configure terminal
9800(config)#
parameter-map type webauth global
9800(config-params-parameter-map)#
virtual-ip ipv4 192.0.2.1
9800(config-params-parameter-map)#
trustpoint CISCO_IDEVID_SUDI

9800(config-params-parameter-map)#
secure-webauth-disable

9800(config-params-parameter-map)#
webauth-http-enable
```

Step 2. Select **+ Add** and configure a name for the new parameter map that points to the external server. Optionally, configure maximum number of HTTP authentication failures before client gets excluded and time (in seconds) that a client can remain in web-authentication state.

Step 3. Select the newly created parameter map, within the **General** tab configure the authentication type from the Type drop down list.

The screenshot shows the 'Edit Web Auth Parameter' dialog with the 'General' tab selected. The 'Parameter-map name' is set to 'EWA-Guest'. Under 'Banner Type', 'None' is selected. 'Maximum HTTP connections' is set to '100' and 'Init-State Timeout(secs)' is set to '120'. The 'Type' dropdown is set to 'consent', with a red box highlighting it. A dropdown menu is open over the 'Type' field, showing options: 'webauth' (selected and highlighted in blue), 'authbypass', 'consent', and 'webconsent'. A red box highlights this dropdown menu. At the bottom, there are 'Cancel' and 'Update & Apply' buttons.

- Parameter-map name = Name assigned to the WebAuth Parameter map
- Maximum HTTP connections = Number of authentication failures before client gets excluded
- Init-State Timeout (secs) = Seconds a client can be on web authentication status
- Type = Type of web authentication

webauth	authbypass	consent	webconsent
<p>Username: <input type="text"/></p> <p>Password: <input type="password"/></p> <p><input type="button" value="OK"/></p>	<p>Client connects to the SSID and gets an IP address, then the 9800 WLC checks if the MAC address is allowed to enter the network, if yes, it is moved to RUN state, if it is not it is not allowed to join.</p> <p>(It does not fall back to web authentication)</p>	<p>banner1</p> <p><input checked="" type="radio"/> Accept</p> <p><input type="radio"/> Don't Accept</p> <p><input type="button" value="OK"/></p>	<p>banner login</p> <p><input checked="" type="radio"/> Accept</p> <p><input type="radio"/> Don't Accept</p> <p>Username: <input type="text"/></p> <p>Password: <input type="password"/></p> <p><input type="button" value="OK"/></p>

Step 4. From the **Advanced** tab configure the Redirect for log-in and Portal IPV4 Address with the specific server site URL and IP address respectively.

Edit Web Auth Parameter

General Advanced

Redirect to external server

Redirect for log-in	http://172.16.80.8/w
Redirect On-Success	
Redirect On-Failure	
Redirect Append for AP MAC Address	ap_mac
Redirect Append for Client MAC Address	client_mac
Redirect Append for WLAN SSID	ssid
Portal IPV4 Address	172.16.80.8
Portal IPV6 Address	X:X:X::X
Express WiFi Key Type	--- Select ---
Customized page	
Login Failed Page	

Cancel **Update & Apply**

Interactive Help

CLI configuration for Steps 2, 3 and 4:

```
<#root>
9800(config)#
parameter-map type webauth EWA-Guest
9800(config-params-parameter-map)#
type consent
9800(config-params-parameter-map)#
redirect for-login http://172.16.80.8/webauth/login.html
9800(config-params-parameter-map)#
redirect portal ipv4 172.16.80.8
```

Step 5. (Optional) WLC can send the additional parameters through Query String. This is often required to make 9800 compatible with third party external portals. The fields "Redirect Append for AP MAC Address", "Redirect Append for Client MAC Address" and "Redirect Append for WLAN SSID" allow additional parameters to be appended to the redirect ACL with a custom name. Select the newly created parameter map and navigate to the **Advanced** tab, configure the name for the necessary parameters. Available parameters are:

- AP MAC Address (in aa:bb:cc:dd:ee:ff format)
- Client MAC Address (in aa:bb:cc:dd:ee:ff format)
- SSID Name

Edit Web Auth Parameter

General Advanced

Redirect to external server

Redirect for log-in	<input type="text" value="http://172.16.80.8/we"/>
Redirect On-Success	<input type="text"/>
Redirect On-Failure	<input type="text"/>
Redirect Append for AP MAC Address	<input type="text" value="ap_mac"/>
Redirect Append for Client MAC Address	<input type="text" value="client_mac"/>
Redirect Append for WLAN SSID	<input type="text" value="ssid"/>

Portal IPV4 Address

Portal IPV6 Address

Express WiFi Key Type

Customized page

Login Failed Page	<input type="text"/>
Login Page	<input type="text"/>
Logout Page	<input type="text"/>
Login Successful Page	<input type="text"/>

Activate Windows
Go to System in Control Panel to activate Windows.

CLI configuration:

```
<#root>
9800(config)#
parameter-map type webauth EWA-Guest

9800(config-params-parameter-map)#
redirect append ap-mac tag ap_mac
```

```
9800(config-params-parameter-map)#
redirect append wlan-ssid tag ssid

9800(config-params-parameter-map)#
redirect append client-mac tag client_mac
```

For this example, redirection URL sent to the client results in:

```
http://172.16.80.8/webauth/consent.html?switch_url=http://192.0.2.1/login.html&ap_mac=&ssid=&client_ma
```

 **Note:** When you add the **Portal IPV4 Address** information it automatically adds an ACL that allows the HTTP and HTTPS traffic from the wireless clients to the external web authentication server, so you do not have to configure any extra pre-auth ACL. In case you would like to allow several IP addresses or URLs, the only option is to configure a URL filter so that any IP matching given URL(s) are allowed before authentication takes place. It is not possible to statically add more than one portal IP address unless you use URL filters.

 **Note:** Global parameter map is the only one where you can define Virtual IPv4 and IPv6 address, Webauth intercept HTTPs, captive bypass portal, watch list enable and watch list expiry timeout settings.

Summary of CLI configuration:

Local web server

```
parameter-map type webauth <web-parameter-map-name>
  type { webauth | authbypass | consent | webconsent }
  timeout init-state sec 300
  banner text ^Cbanner login^C
```

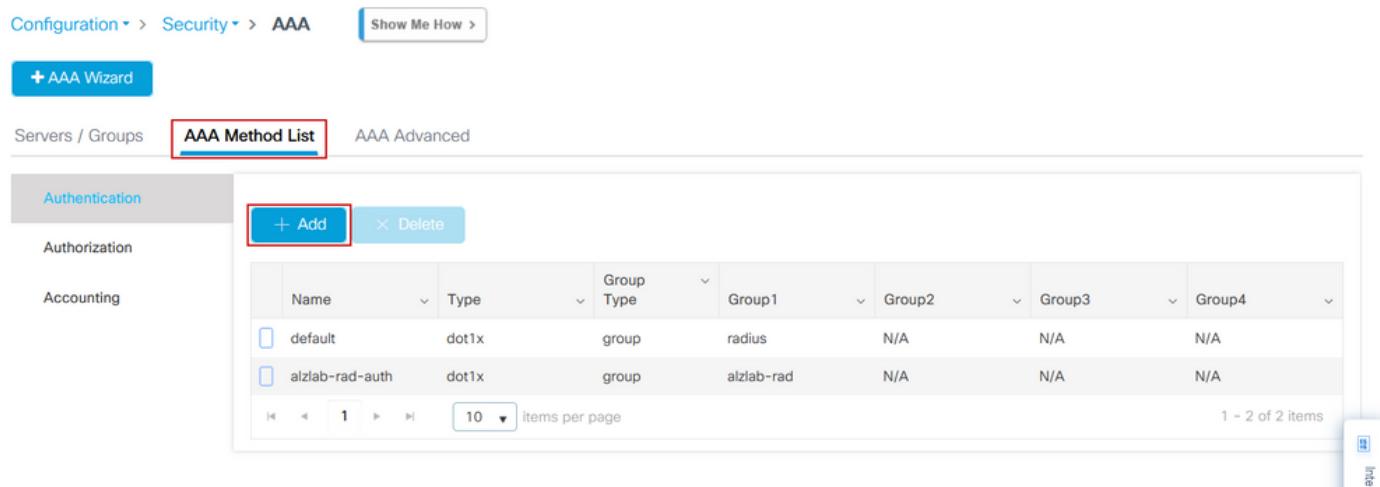

External web server

```
parameter-map type webauth <web-parameter-map-name>
  type webauth
  timeout init-state sec 300
  redirect for-login <URL-for-webauth>
  redirect portal ipv4 <external-server's-IP>
  max-http-conns 10
```

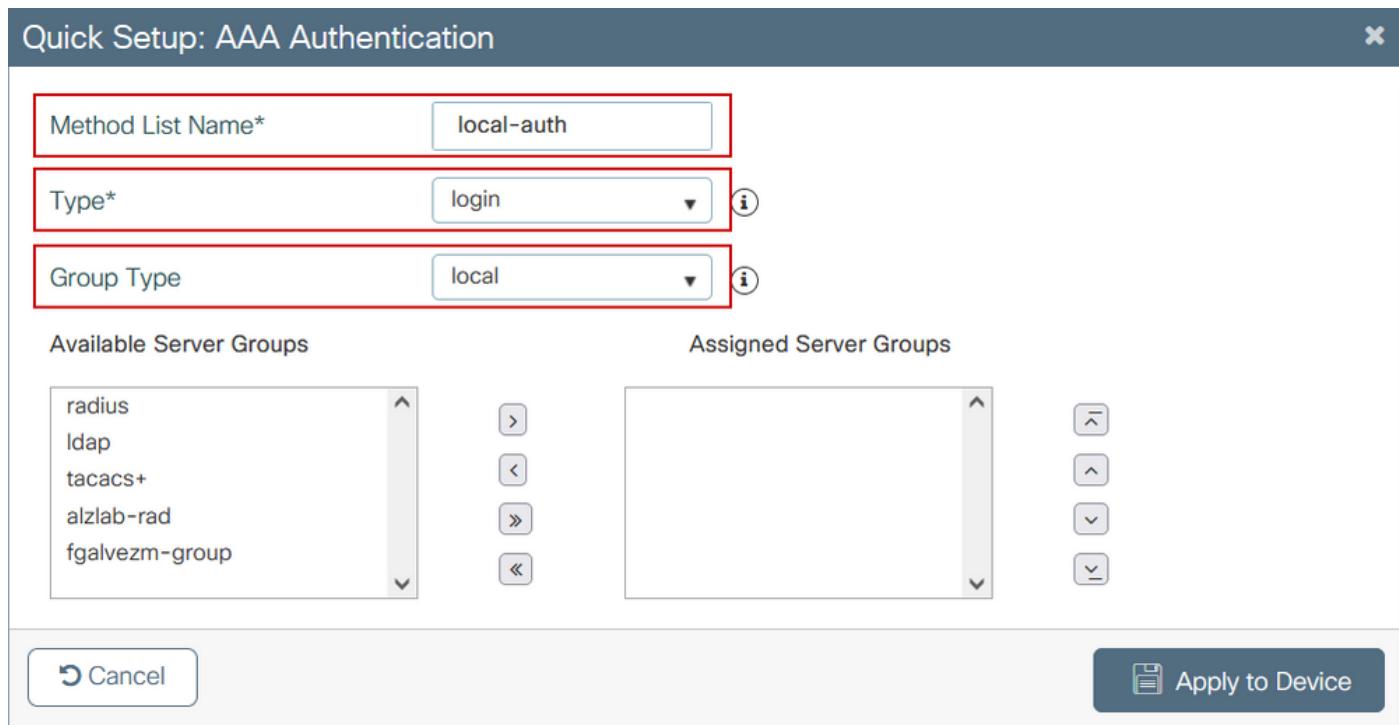

Configure AAA Settings

This configuration section is only needed for parameters maps that are configured for either webauth or webconsent authentication type.

Step 1. Navigate to **Configuration > Security > AAA**, then select **AAA Method List**. Configure a new method list, select **+ Add** and fill in the list details; ensure that Type is set to "login" as shown in the image.

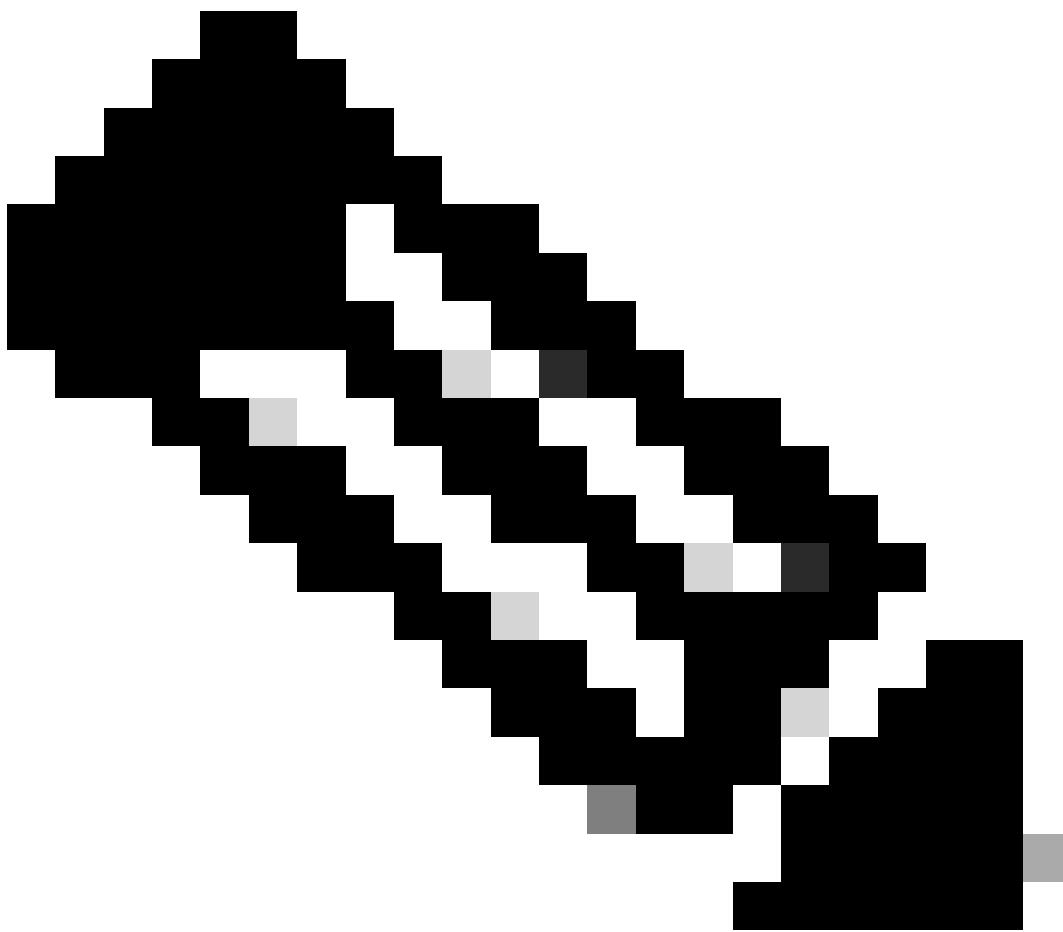

The screenshot shows the 'AAA Method List' configuration page. At the top, there are tabs for 'Servers / Groups', 'AAA Method List' (which is selected and highlighted with a red box), and 'AAA Advanced'. Below the tabs is a navigation bar with 'Authentication', 'Authorization', and 'Accounting' buttons. A large table lists the current method entries. The first entry is 'default' (Type: dot1x, Group Type: group, Group1: radius, Group2: N/A, Group3: N/A, Group4: N/A). The second entry is 'alzlab-rad-auth' (Type: dot1x, Group Type: group, Group1: alzlab-rad, Group2: N/A, Group3: N/A, Group4: N/A). Below the table are buttons for '+ Add' (highlighted with a red box) and 'Delete'. At the bottom, there are pagination controls (1 of 2 items per page) and a status message '1 - 2 of 2 items'.

The screenshot shows the 'Quick Setup: AAA Authentication' dialog box. It has three main sections: 'Method List Name*' (set to 'local-auth'), 'Type*' (set to 'login'), and 'Group Type' (set to 'local'). Below these are two lists: 'Available Server Groups' (containing 'radius', 'ldap', 'tacacs+', 'alzlab-rad', and 'fgalvezm-group') and 'Assigned Server Groups' (empty). Between the lists are four arrows for moving items between them. At the bottom are 'Cancel' and 'Apply to Device' buttons.

Step 2. Select **Authorization** and then select **+ Add** to create a new method list. Name it default with Type as network as shown in the image.

Note: As it is advertised by the controller during the [WLAN layer 3 security configuration](#): *For Local Login Method List to work, please make sure the configuration 'aaa authorization network default local' exists on the device.* This means that the authorization method list with name **default** must be defined in order to configure local web-authentication properly. In this section, this particular authorization method list is configured.

Configuration > Security > AAA [Show Me How >](#)

radius	<	>	<<	>>	<=	>=
ldap						
tacacs+						
alzlab-rad						
fgalvezm-group						

Cancel Apply to Device

CLI configuration for Steps 1 and 2:

```
<#root>  
9800(config)#  
aaa new-model  
  
9800(config)#  
aaa authentication login local-auth local  
  
9800(config)#  
aaa authorization network default local
```

 **Note:** If external RADIUS authentication is necessary, please read these instructions related to RADIUS server configuration on 9800 WLCs: [AAA Config on 9800 WLC](#). Ensure that the authentication method list has "login" set as type instead of dot1x.

Step 3. Navigate to **Configuration > Security > Guest User**. Select **+ Add** and configure guest user account details.

Add Guest User

General		Lifetime	
User Name*	guestuser	Years*	1
Password*	***** 	Months*	0
<input type="checkbox"/> Generate password		Days*	0
Confirm Password*	*****	Hours*	0
Description*	WebAuth user	Mins*	0
AAA Attribute list	Enter>Select		
No. of Simultaneous User Logins*	0 <small>Enter 0 for unlimited users</small>		
<input type="button" value="Cancel"/>		 <input type="button" value="Apply to Device"/>	

CLI configuration:

```
<#root>
9800(config)#
user-name guestuser

9800(config-user-name)#
description "WebAuth user"

9800(config-user-name)#
password 0 <password>

9800(config-user-name)#
type network-user description "WebAuth user" guest-user lifetime year 1
```

If permanent users are needed then use this command:
9800(config)#

```
username guestuserperm privilege 0 secret 0 <password>
```

Step 4. (Optional) Upon parameter map definition, a couple of access control lists (ACLs) are automatically created. These ACLs are used to define which traffic triggers a redirection to web server and which traffic is allowed to pass through. If specific requirements, such as multiple web server IP addresses or URL filters,

exist, then navigate to **Configuration > Security > ACL** select + **Add** and define necessary rules; permit statements are redirected while deny statements define traffic passes through.

Automatically created ACLs rules are:

```
<#root>
alz-9800#
show ip access-list

Extended IP access list WA-sec-172.16.80.8
10 permit tcp any host 172.16.80.8 eq www
20 permit tcp any host 172.16.80.8 eq 443
30 permit tcp host 172.16.80.8 eq www any
40 permit tcp host 172.16.80.8 eq 443 any
50 permit tcp any any eq domain
60 permit udp any any eq domain
70 permit udp any any eq bootpc
80 permit udp any any eq bootps
90 deny ip any any (1288 matches)
Extended IP access list WA-v4-int-172.16.80.8
10 deny tcp any host 172.16.80.8 eq www
20 deny tcp any host 172.16.80.8 eq 443
30 permit tcp any any eq www
40 permit tcp any host 192.0.2.1 eq 443
```

Configure Policies and Tags

Step 1. Navigate to **Configuration > Tags & Profiles > WLANs**, select + **Add** to create a new WLAN. Define profile and SSID name, and Status in the **General** tab.

Profile Name*	EWA-Guest
SSID*	EWA-Guest
WLAN ID*	4
Status	ENABLED

Radio Policy: All

Broadcast SSID: ENABLED

General Security Advanced

Cancel Apply to Device

Step 2. Select **Security** tab and set Layer 2 authentication to None if you do not need any over the air encryption mechanism. In the Layer 3 tab, check the Web Policy box, select the parameter map from drop-down menu, and chose the authentication list from the drop-down menu. Optionally, if a custom ACL was defined earlier, select **Show Advanced Settings** and select the appropriate ACL from the drop-down menu.

⚠ Changing WLAN parameters while it is enabled will result in loss of connectivity for clients connected to it.

Interactive Help □

If multiple APs need to be tagged at the same time, then there are two available options:

Option A. Navigate to **Configuration > Wireless Setup > Advanced** from there select **Start Now** to display the configuration menu list. Select the list icon next to **Tag APs**, this displays the list of all APs in Join state, check the necessary APs and then select **+ Tag APs**, select the created Policy Tag from the drop down menu.

Wireless Setup Flow Overview

Troubleshoot

Always-On Tracing

WLC 9800 provides ALWAYS-ON trace capabilities. This ensures all client connectivity related errors, warning, and notice level messages are constantly logged and you can view logs for an incident or failure condition after it has occurred.

 **Note:** Based on the volume of logs generated you can go back from few hours to several days.

In order to view the traces that 9800 WLC collected by default, you can connect via SSH/Telnet to the 9800 WLC and read these steps (ensure you log the session to a text file).

Step 1. Check the controller current time so you can track the logs in the time back to when the issue happened.

```
<#root>  
9800#  
show clock
```

Step 2. Collect syslogs from the controller buffer or the external syslog as dictated by the system configuration. This provides a quick view of the system health and errors if any.

```
<#root>  
9800#  
show logging
```

Step 3. Verify if any debug conditions are enabled.

```
<#root>  
9800#  
show debugging  
  
IOSXE Conditional Debug Configs:  
Conditional Debug Global State: Stop  
IOSXE Packet Tracing Configs:  
Packet Infra debugs:  
Ip Address Port  
-----|-----
```

 **Note:** If you see any condition listed, it means the traces are logged up to debug level for all the processes that encounter the enabled conditions (mac address, IP address, and so on). This would increase the volume of logs. Therefore, it is recommended to clear all conditions when not actively debugging.

Step 4. With the assumption that the mac address under test was not listed as a condition in Step 3. Collect the always-on notice level traces for the specific mac address.

```
<#root>
9800#
show logging profile wireless filter [mac | ip] [<aaaa.bbbb.cccc> | <a.b.c.d>] to-file always-on-<FILENAME>
```

You can either display the content on the session or you can copy the file to an external TFTP server.

```
<#root>
9800#
more bootflash:always-on-<FILENAME.txt>

or
9800#
copy bootflash:always-on-<FILENAME.txt> tftp://<a.b.c.d>/<path>/always-on-<FILENAME.txt>
```

Conditional Debugging and Radio Active Tracing

If the always-on traces do not give you enough information in order to determine the trigger for the problem under investigation, you can enable conditional debugging and capture Radio Active (RA) trace, which provides debug level traces for all processes that interact with the specified condition (client mac address in this case). In order to enable conditional debugging, read these steps.

Step 1. Ensure there are no debug conditions are enabled.

```
<#root>
9800#
clear platform condition all
```

Step 2. Enable the debug condition for the wireless client mac address that you want to monitor.

These commands start to monitor the provided mac address for 30 minutes (1800 seconds). You can optionally increase this time to up to 2085978494 seconds.

```
<#root>
```

```
9800#  
debug wireless mac <aaaa.bbbb.cccc> {monitor-time <seconds>}
```

 **Note:** In order to monitor more than one client at a time, run debug wireless mac command per mac address.

 **Note:** The wireless client activity is not displayed on the terminal session as all the logs are buffered internally in order to be viewed later.

Step 3. Reproduce the issue or behavior that you want to monitor.

Step 4. Stop the debugs if the issue is reproduced before the default or configured monitor time is up.

```
<#root>  
9800#  
no debug wireless mac <aaaa.bbbb.cccc>
```

Once the monitor-time has elapsed or the debug wireless has been stopped, the 9800 WLC generates a local file with the name:

ra_trace_MAC_aaaabbbbcccc_HHMMSS.XXX_timezone_DayWeek_Month_Day_year.log

Step 5. Collect the file of the mac address activity. You can either copy the ra trace .log to an external server or display the output directly on the screen.

Check the name of the RA traces file.

```
<#root>  
9800#  
dir bootflash: | inc ra_trace
```

Copy the file to an external server:

```
<#root>  
9800#  
copy bootflash:ra_trace_MAC_aaaabbbbcccc_HHMMSS.XXX_timezone_DayWeek_Month_Day_year.log tftp://<a.b.c.d>
```

Display the content:

```
<#root>
```

```
9800#
```

```
more bootflash:ra_trace_MAC_aaaabbbbcccc_HHMMSS.XXX_timezone_DayWeek_Month_Day_year.log
```

Step 6. If the root cause is still not obvious, collect the internal logs which are a more verbose view of debug level logs. You do not need to debug the client again as the command provides debug logs that have been already collected and internally stored.

```
<#root>
```

```
9800#
```

```
show logging profile wireless internal filter [mac | ip] [<aaaa.bbbb.cccc> | <a.b.c.d>] to-file ra-inter
```

 **Note:** This command output returns traces for all logging levels for all processes and is quite voluminous. Please contact Cisco TAC in order to help parse through these traces.

```
<#root>
```

```
9800#
```

```
copy bootflash:ra-internal-<FILENAME>.txt tftp://<a.b.c.d>/ra-internal-<FILENAME>.txt
```

Display the content:

```
<#root>
```

```
9800#
```

```
more bootflash:ra-internal-<FILENAME>.txt
```

Step 7. Remove the debug conditions.

 **Note:** Ensure that you always remove the debug conditions after a troubleshoot session.

Embedded Packet Captures

9800 controllers can sniff packets natively; this allows for easier troubleshoot as control plane packet processing visibility.

Step 1. Define an ACL to filter traffic of interest. For web-authentication, it is recommended to allow traffic from and to the web server, as well as traffic from and to a couple of APs where clients are connected.

```
<#root>
```

```
9800(config)#
```

```

ip access-list extended EWA-pcap

9800(config-ext-nacl)#
permit ip any host <web server IP>

9800(config-ext-nacl)#
permit ip host <web server IP> any

9800(config-ext-nacl)#
permit ip any host <AP IP>

9800(config-ext-nacl)#
permit ip host <AP IP> any

```

Step 2. Define the monitor capture parameters. Ensure that control plane traffic is enabled in both directions, interface refers to the physical uplink of your controller.

```

<#root>

9800#
monitor capture EWA buffer size <buffer size in MB>

9800#
monitor capture EWA access-list EWA-pcap

9800#
monitor capture EWA control-plane both interface <uplink interface> both

```

```

<#root>

9800#
show monitor capture EWA

Status Information for Capture EWA
Target Type:
Interface: Control Plane, Direction: BOTH
Interface: TenGigabitEthernet0/1/0, Direction: BOTH

Status : Inactive
Filter Details:

Access-list: EWA-pcap

Inner Filter Details:

```

Buffer Details:

Buffer Type: LINEAR (default)

Buffer size (in MB): 100

Limit Details:

Number of Packets to capture: 0 (no limit)

Packet Capture duration: 0 (no limit)

Packet Size to capture: 0 (no limit)

Packet sampling rate: 0 (no sampling)

Step 3. Start the monitor capture and reproduce the issue.

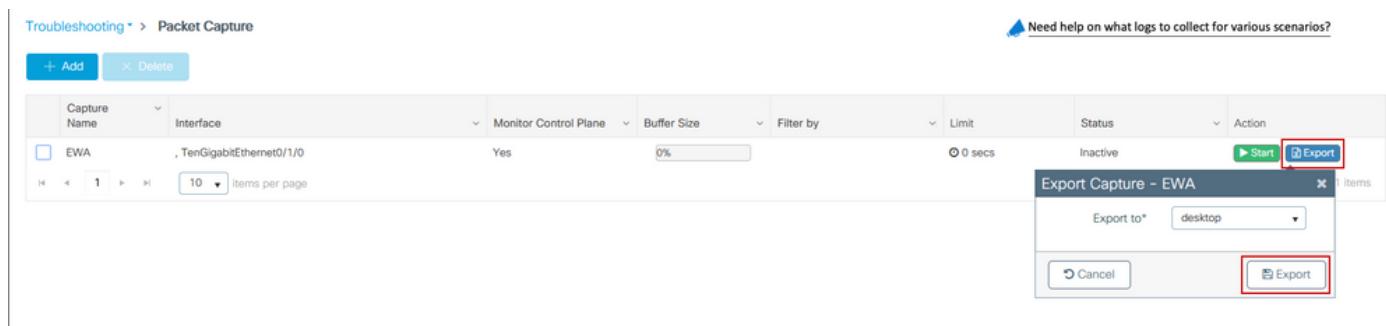

```
<#root>  
9800#  
monitor capture EWA start
```

Started capture point : EWA

Step 4. Stop the monitor capture and export it.

```
<#root>  
9800#  
monitor capture EWA stop  
  
Stopped capture point : EWA  
9800#monitor capture EWA export tftp://<a.b.c.d>/EWA.pcap
```

Alternatively, the capture can be downloaded from GUI, navigate to **Troubleshooting > Packet Capture** and select **Export** on the configured capture. Select desktop from drop-down menu to download the capture through HTTP into the desired folder.

The screenshot shows the Cisco Packet Capture interface under the Troubleshooting section. A table lists a single capture named 'EWA' with the interface set to 'TenGigabitEthernet0/1/0'. The status is 'Inactive'. There are 'Start' and 'Export' buttons. An 'Export Capture - EWA' dialog box is open over the table, with the 'Export to*' dropdown set to 'desktop'. Both the 'Cancel' and 'Export' buttons in the dialog box are highlighted with red boxes.

Client Side Troubleshoot

Web authentication WLANs are dependant on client behavior, upon this basis, client-side behavior

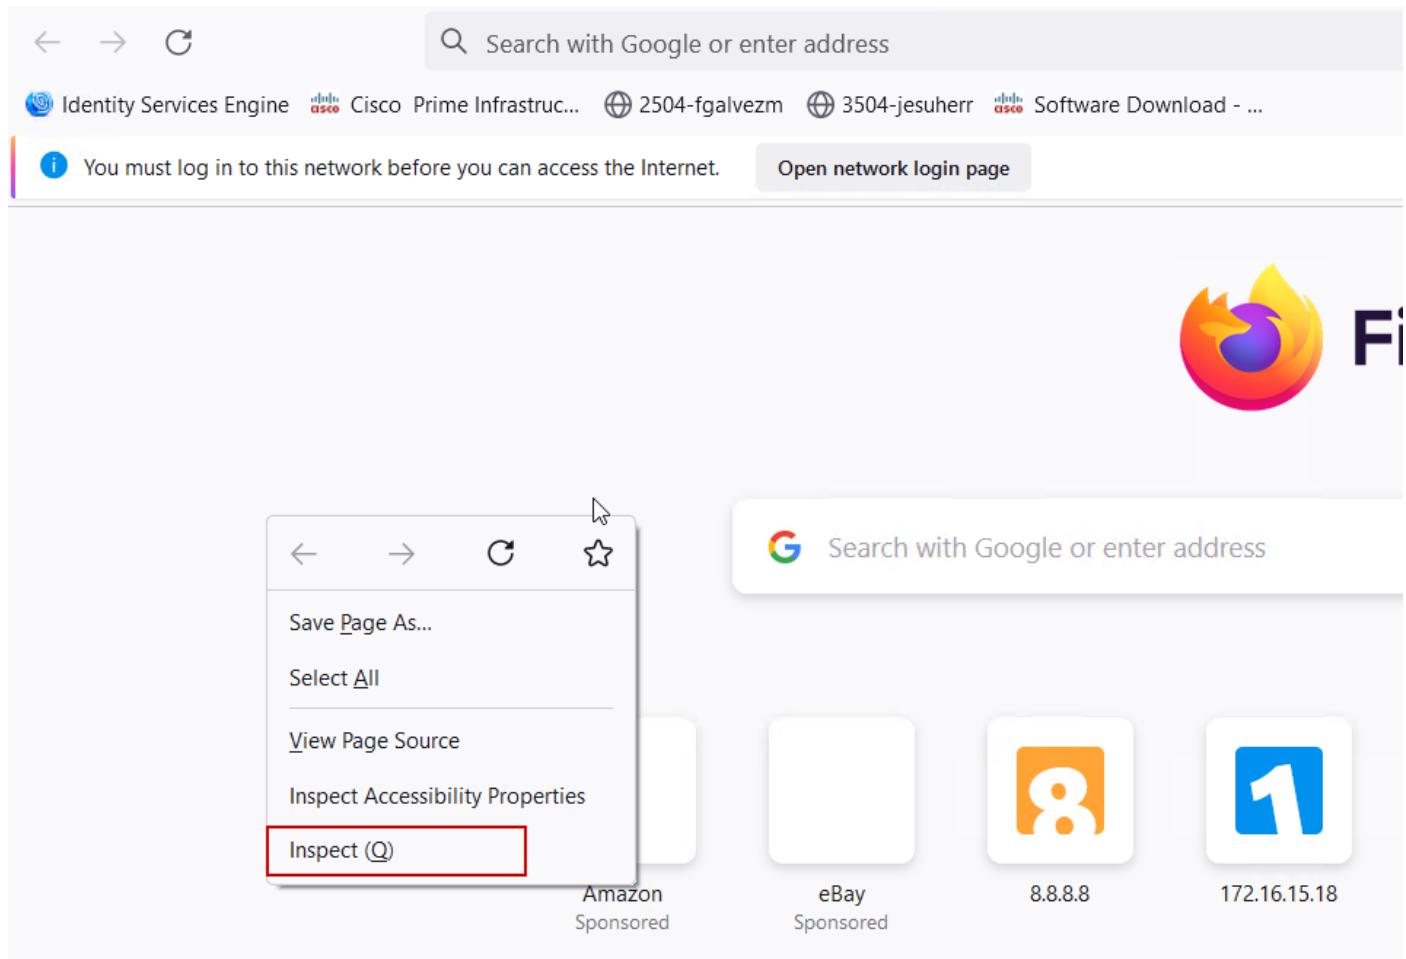

knowledge and information is key to identify root cause of web authentication misbehaviors.

HAR Browser Troubleshoot

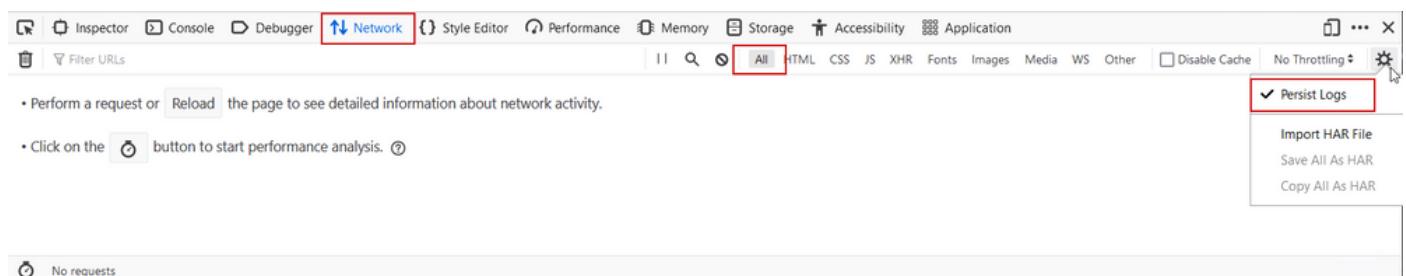

Many modern browsers, such as Mozilla Firefox and Google Chrome, provide console developer tools to debug web application interactions. HAR files are records of client-server interactions and provide a timeline of HTTP interactions along with request and response information (headers, status code, parameters, and so on).

HAR files can be exported from the client browser and imported on a different browser for further analysis. This document outlines how to collect the HAR file from Mozilla Firefox.

Step 1. Open Web Developer Tools with **Ctrl + Shift + I**, alternatively right-click within the browser content and select **Inspect**.

Step 2. Navigate to **Network**, ensure that "All" is selected to capture all request types. Select the gear icon and ensure that **Persist Logs** has an arrow next to it, otherwise logs request are cleared whenever a domain change is triggered.

Step 3. Reproduce the issue, ensure that browser logs all requests. Once, issue is reproduced stop network logging, then select on the gear icon and select **Save All As HAR**.

Client Side Packet Capture

Wireless clients with OS such as Windows or MacOS can sniff packets on their wireless card adapter. While not a direct replacement of over-the-air packet captures, they can provide a glance on the overall web authentication flow.
